John Bergschneider

Classifying 2-stratifolds with Finite Fundamental Group

Ex   Glue $(S^1 \times I)^2$ by a rotation
      Identify some fibers
      Fill w/ 2-cells
          ↳ It def. retracts onto this

Represent branched nbhds as graphs where nodes = fibers
and edge labels = # times wrapped around singular curve.
   ↳ Presentation of π_1
Color vertices black iff singular, else white

Finite 2-strat groups: Fuchsian

Graph types: Tree w/ almost all white vertices
                            genus zero

Each trivalent 2-strat contains a star-strat
that generates π_1.

         — Dense in embeddings into mfds

         Similar to trisections for 4-mfds
